BACKGROUND

- Chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL) are the most common types of leukemia in adults in the US
- The US veteran population, predominantly older males, are at high risk for CLL/SLL, especially with prior exposure to Agent Orange or other herbicides during military service
- With the increasing availability of novel agents and associated improved survival, there is a need to assess the real-world evidence of CLL/SLL burden in US veterans, and the clinical and economic outcomes associated with current treatments

OBJECTIVE

 To examine the clinical burden, costs and healthcare resource utilization of US veterans with CLL/SLL

METHODS

- **Study design:** Retrospective, observational study
- Data source: Veteran Health Administration dataset
- Study period: October 2014 September 2019
- Study population:
- Adults who were newly diagnosed with CLL/SLL
- Index date: the first CLL/SLL diagnosis date during the identification period (April 2014
 July 2018)
- Aged ≥18 years at index date
- ≥2 diagnosis of CLL/SLL (ICD-9-CM: 204.1, 200.8 or ICD-10-CM: C91.1, C83.0) on different days during the identification period
- Continuous enrollment of 6 months pre- and 3 months post-index date
- ≥ 1 CLL/SLL treatment on or after the index date
- No CLL/SLL treatment any time prior to the index date

Treatment regimens and patterns:

- Classified according to NCCN guidelines and identified using HCPCS and NDC codes
- 5 mutually exclusive categories of CLL/SLL treatment regimen:
- Bendamustine-based (alone or in combination) therapy
- Other chemotherapies
- Ibrutinib
- Rituximab-monotherapy
- Other regimens
- Treatment patterns evaluated by frequency and duration of treatment regimen, and by lines of therapy

• Adherence:

- Treatment duration: The total number of days from the first day of a line of therapy to the last drug prescription date, plus derived days of supply for injectable drugs or days of supply for oral drugs of the respective line of therapy
- <u>Discontinuation</u>: Defined as a treatment gap of more than 90 days from the last day of supply
- Switching: Any new WM treatment >60 days after the start of a line of therapy

• Economic outcomes:

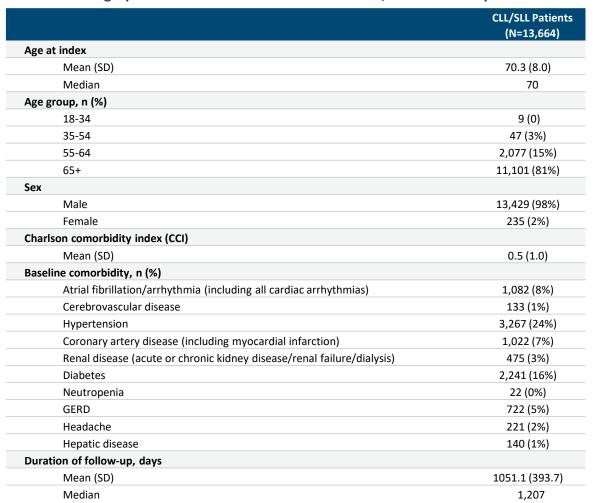

- Healthcare resource utilization: Frequency and duration of inpatient hospital admissions, outpatient visits, and pharmacy visits
- Total costs: Calculated as the sum of inpatient, outpatient, and pharmacy costs perpatient-per-month (PPPM)

RESULTS

Patient characteristics:

- Of 13,664 veteran patients diagnosed with CLL/SLL, 79% were in watch-and-wait
- Final study population consisted of 2,861 patients who received ≥1 line of CLL/SLL therapy (mean duration = 465 days)
- Most patients were elderly (median age= 70 years), white (83%), and male (98%)
- Approximately 39% of veterans had concurrent use of proton pump inhibitors at baseline

Table 1. Demographic and Clinical Characteristics of CLL/SLL Patient Population

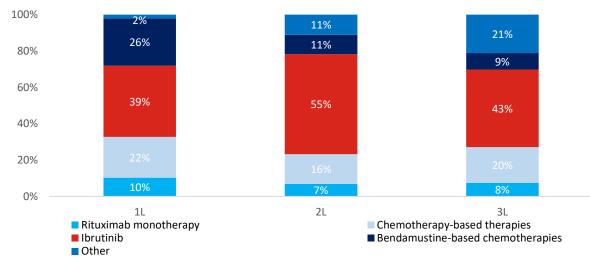

Abbreviations: GERD, gastroesophageal reflux disease; SD, standard deviation;

Treatment patterns:

- Average time to treatment initiation from diagnosis to first-line therapy was 315 days
- 770 (26.9%) patients who received first-line (1L) therapy further received second-line
 (2L) therapy (mean duration of treatment=318 days), and 199 (7.0%) patients
 received third-line (3L) therapy (mean duration of treatment=229 days)
- Ibrutinib was the most common treatment regimen across all lines of therapy (1L: 39%; 2L: 55%; 3L: 43%) (Figure 1)

Figure 1. Treatment Patterns Among CLL/SLL patients by Line of Therapy

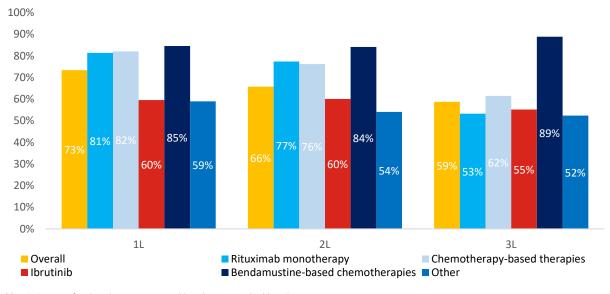

Abbreviations: 1L, first-line therapy; 2L, second-line therapy; 3L, third-line therapy

RESULTS

Treatment discontinuation:

- Overall, treatment discontinuation rates were high across current regimens in each line of therapy (1L: 73% [mean duration: 354 days], 2L: 66% [mean duration: 241 days], 3L: 59% [mean duration:190 days]) (Figure 2)
- Discontinuation rates were generally highest for bendamustine-based chemotherapies, with 85%, 84% and 89% discontinuing in 1L, 2L, and 3L, respectively
- Ibrutinib accounts for over half of total patient discontinuations during treatment;
 discontinuation rates at 60%, 60%, and 55% in 1L, 2L, and 3L, respectively

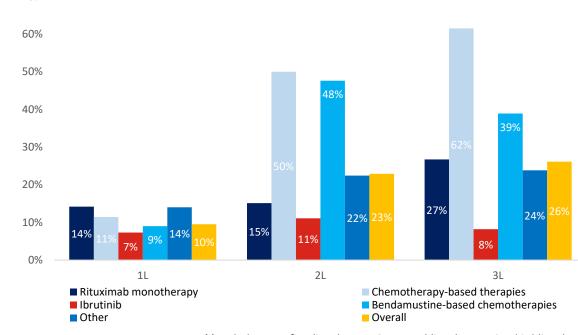

Figure 2. Treatment Discontinuation Rates by Line of Therapy

Abbreviations: 1L, first-line therapy; 2L, second-line therapy; 3L, third-line therapy

 Treatment switch: The overall treatment switching rate was highest in 3L (26%), followed by 23% in 2L and 10% in 1L therapies (Figure 3)

Figure 3. Treatment Switch Rates by Line of Therapy

Abbreviations: 1L, first-line therapy; 2L, second-line therapy; 3L, third-line therapy

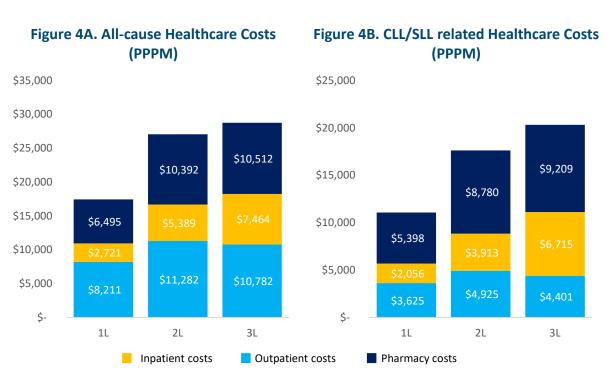

• Healthcare resource utilization and costs:

- The CLL/SLL-related hospitalization rate was 39%, with an average LOS of 7 days (Table
 2)
- Total PPPM all-cause- and CLL/SLL-related costs were \$26,709 and \$17,233,
 respectively; these costs were increased by line of therapy (Figure 4A and Figure 4B)
- Controlling for patient clinical and demographic covariates, treatment discontinuation and treatment switching were statistically significant predictors of higher inpatient admissions and LOS of hospitalizations

RESULTS

Table 2. All-Cause Health Resource Utilization

Frequency (Per-Patient Per-Month)	Overall Treated (N=2,861)	1L (n=2,861)	2L (n=770)	3L (n=199)
Outpatient visits (Mean ± SD)	7.69 ± 5.07	5.62 ± 2.74	6.07 ± 5.58	6.19 ± 3.06
Inpatient admissions (Mean ± SD)	0.05 ± 0.30	0.02 ± 0.18	0.07 ± 0.43	0.08 ± 0.37
Pharmacy visits (Mean ± SD)	5.74 ± 5.06	4.05 ± 3.06	4.93 ± 4.40	5.19 ± 4.00
Duration of hospitalization (Length of stay, days) (Mean ± SD)	1.04 ± 3.66	0.64 ± 2.71	1.14 ± 3.78	1.46 ± 4.80

DISCUSSION

- This study evaluated the real-world utilization of treatment regimens by line of therapy in newly diagnosed CLL/SLL patients in the US. Results reflected the variation of real-world treatment patterns from clinical treatment guidelines
- Study limitations were inherent to the use of claims databases in an observational study design
- Future studies are needed to further understand factors associated with treatment selection and outcomes

CONCLUSION

- This real-world data demonstrated significant clinical and economic burden associated with CLL/SLL among the US veterans
- Furthermore, the suboptimal adherence, as reported by high treatment discontinuation rates and its impact on increasing costs and healthcare resource use, highlights the real-world unmet needs of CLL/SLL management in the veteran population
